- Introduction
- Error detection, correction
- Multiple access protocols
- LANs
- Link virtualization: MPLS
- Data center networking
- A day in the life of a web request

terminology:

- hosts, routers: nodes
- communication channels that connect adjacent nodes along communication path: links
 - wired , wireless
 - LANs
- layer-2 packet: frame, encapsulates datagram

link layer has responsibility of transferring datagram from one node to physically adjacent node over a link

- datagram transferred by different link protocols over different links:
 - e.g., WiFi on first link,
 Ethernet on next link
- each link protocol provides different services
 - e.g., may or may not provide reliable data transfer over link

Transportation analogy

transportation analogy:

- trip from Princeton to Lausanne
 - limo: Princeton to JFK
 - > plane: JFK to Geneva
 - Train: Geneva to Lausanne
- tourist = datagram
- transport segment = communication link
- transportation mode = link-layer protocol
- travel agent = routing algorithm

- framing, link access:
 - encapsulate datagram into frame, adding header, trailer
 - channel access if shared medium
 - "MAC" addresses in frame headers identify source, destination (different from IP address!)
 - reliable delivery between adjacent nodes
 - > we already know how to do this!
 - seldom used on low bit-error links
 - wireless links: high error rates
 - Q: why both link-level and end-end reliability?

Link layer: services (more)

- flow control:
 - pacing between adjacent sending and receiving nodes
- error detection:
 - > errors caused by signal attenuation, noise.
 - receiver detects errors, signals retransmission, or drops frame
- error correction:
 - receiver identifies and corrects bit error(s) without retransmission
- half-duplex and full-duplex:
 - with half duplex, nodes at both ends of link can transmit, but not at same time

- in each-and-every host
- link layer implemented on-chip or in network interface card (NIC)
 - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

sending side:

- encapsulates datagram in frame
- adds error checking bits, reliable data transfer, flow control, etc.

receiving side:

- looks for errors, reliable data transfer, flow control, etc.
- extracts datagram, passes to upper layer at receiving side

NANJING UNIVERSITY

- Introduction
- Error detection, correction
- Multiple access protocols
- LANs
- Link virtualization: MPLS
- Data center networking
- A day in the life of a web request

EDC: error detection and correction bits (e.g., redundancy) D: data protected by error checking, may include header fields

Error detection not 100% reliable!

- protocol may miss some errors, but rarely
- larger EDC field yields better detection and correction

single bit parity:

detect single bit errors

0111000110101011 1

🛏 d data bits 🗕

parity bit

Even/odd parity: set parity bit so there is an even/odd number of 1's

- At receiver:
- compute parity of d received bits
- compare with received parity bit - if different than error detected

Can detect and correct errors (without retransmission!)

 two-dimensional parity: detect and correct single bit errors

Goal: detect errors (i.e., flipped bits) in transmitted segment

sender:

- treat contents of UDP segment (including UDP header fields and IP addresses) as sequence of 16-bit integers
- checksum: addition (one's complement sum) of segment content
- checksum value put into UDP checksum field

receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
 - not equal error detected
 - equal no error detected. But maybe errors nonetheless? More later

- more powerful error-detection coding
- D: data bits (given, think of these as a binary number)
- G: bit pattern (generator), of r+1 bits (given, specified in CRC standard)

sender: compute r CRC bits, R, such that <D,R> exactly divisible by G (mod 2)

- receiver knows G, divides < D,R> by G. If non-zero remainder: error detected!
- can detect all burst errors less than r+1 bits
- widely used in practice (Ethernet, 802.11 WiFi)

_____ Cyclic Redundancy Check (CRC): example

- Introduction
- Error detection, correction
- Multiple access protocols
- LANs
- Link virtualization: MPLS
- Data center networking
- A day in the life of a web request

two types of "links":

- point-to-point
 - point-to-point link between Ethernet switch, host
 - PPP for dial-up access
- broadcast (shared wire or medium)
 - old-school Ethernet
 - upstream HFC in cable-based access network
 - > 802.11 wireless LAN, 4G/4G. satellite

(shared air, acoustical)

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
 collision if node receives two or more signals at the same time
- multiple access protocol
 - distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
 - communication about channel sharing must use channel itself!
 > no out-of-band channel for coordination

given: multiple access channel (MAC) of rate R bps desiderata:

- 1. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate $\ensuremath{\mathsf{R}}\xspace/\ensuremath{\mathsf{M}}\xspace$
- 3. fully decentralized:
 - > no special node to coordinate transmissions
 - > no synchronization of clocks, slots
- 4. simple

three broad classes:

- channel partitioning
 - divide channel into smaller "pieces" (time slots, frequency, code)
 - > allocate piece to node for exclusive use
- random access
 - channel not divided, allow collisions
 - "recover" from collisions
- "taking turns"
 - nodes take turns, but nodes with more to send can take longer turns

TDMA: time division multiple access

- access to channel in "rounds"
- each station gets fixed length slot (length = packet transmission time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have packets to send, slots 2,5,6 idle

Channel partitioning MAC protocols: FDMA

FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have packet to send, frequency bands 2,5,6 idle

- when node has packet to send
 - transmit at full channel data rate R
 - > no a priori coordination among nodes
- two or more transmitting nodes: "collision"
- random access protocol specifies:
 - how to detect collisions
 - > how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
 - > ALOHA, slotted ALOHA
 - > CSMA, CSMA/CD, CSMA/CA

assumptions:

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

operation:

- when node obtains fresh frame, transmits in next slot
 - if no collision: node can send new frame in next slot
 - if collision: node retransmits frame in each subsequent slot with probability puntil success

randomization - why?

ANJING UNIVERSIT

Pros:

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

Cons:

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

- suppose: N nodes with many frames to send, each transmits in slot with probability p
 - prob that given node has success in a slot = $p(1-p)^{N-1}$
 - prob that any node has a success = $Np(1-p)^{N-1}$
 - max efficiency: find p^* that maximizes Np(1-p)^{N-1}

– for many nodes, take limit of Np*(1-p*)^{N-1} as N goes to infinity, gives: max efficiency = 1/e = .37

• at best: channel used for useful transmissions 37% of time!

simple CSMA: listen before transmit:

- > if channel sensed idle: transmit entire frame
- if channel sensed busy: defer transmission
- human analogy: <u>don't interrupt others!</u>

CSMA/CD: CSMA with collision detection

- collisions detected within short time
- > colliding transmissions aborted, reducing channel wastage
- > collision detection easy in wired, difficult with wireless
- human analogy: the polite conversationalist

- collisions can still occur with carrier sensing:
 - propagation delay means two nodes may not hear each other's just-started transmission
- collision: entire packet transmission time wasted
 - distance & propagation delay play role in in determining collision probability

time

t₁

- CSMA/CD reduces the amount of time wasted in collisions
 - transmission aborted on collision detection

- 1. Ethernet receives datagram from network layer, creates frame
- 2. If Ethernet senses channel:
 - if idle: start frame transmission.
 - if busy: wait until channel idle, then transmit
- 3. If entire frame transmitted without collision done!
- 4. If another transmission detected while sending: abort, send jam signal
- 5. After aborting, enter binary (exponential) backoff:
 - after mth collision, chooses K at random from {0,1,2, ..., 2^m-1}.
 Ethernet waits K[.]512 bit times, returns to Step 2
 - more collisions: longer backoff interval

"Taking turns" MAC protocols

channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

"taking turns" protocols

look for best of both worlds!

"Taking turns" MAC protocols

polling:

- centralized controller "invites" other nodes to transmit in turn
- typically used with "dumb" devices
- concerns:
 - polling overhead
 - > latency
 - > single point of failure (master)
- Bluetooth uses polling

"Taking turns" MAC protocols

token passing:

- control token message explicitly passed from one node to next, sequentially
 - transmit while holding token
- concerns:
 - token overhead
 - > latency
 - single point of failure (token)

- multiple downstream (broadcast) FDM channels: up to 1.6 Gbps/channel
 > single CMTS transmits into channels
- multiple upstream channels (up to 1 Gbps/channel)
 - multiple access: all users contend (random access) for certain upstream channel time slots; others assigned TDM

DOCSIS: data over cable service interface specification

- FDM over upstream, downstream frequency channels
- TDM upstream: some slots assigned, some have contention
 - downstream MAP frame: assigns upstream slots
 - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

- Introduction
- Error detection, correction
- Multiple access protocols
- LANs
- Link virtualization: MPLS
- Data center networking
- A day in the life of a web request

- 32-bit IP address:
 - network-layer address for interface
 - > used for layer 3 (network layer) forwarding
 - ▶ e.g.: 128.119.40.136
- MAC (or LAN or physical or Ethernet) address:
 - function: used "locally" to get frame from one interface to another physically-connected interface (same subnet, in IP-addressing sense)
 - > 48-bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
 - e.g.: 1A-2F-BB-76-09-AD

hexadecimal (base 16) notation
(each "numeral" represents 4 bits)

each interface on LAN

- has unique 48-bit MAC address
- has a locally unique 32-bit IP address (as we've seen)

NANJING UNIVERSIT

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
 - > MAC address: like Social Security Number
 - > IP address: like postal address
- MAC flat address: portability
 - > can move interface from one LAN to another
 - recall IP address not portable: depends on IP subnet to which node is attached

ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
 - < IP address; MAC address; TTL>

 TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

example: A wants to send datagram to B

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

example: A wants to send datagram to B

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

example: A wants to send datagram to B

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

walkthrough: sending a datagram from A to B via R

- focus on addressing at IP (datagram) and MAC layer (frame) levels
- assume that:
 - > A knows B's IP address
 - > A knows IP address of first hop router, R (how?)
 - > A knows R's MAC address (how?)

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame containing A-to-B IP datagram
 - R's MAC address is frame's destination

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- B receives frame, extracts IP datagram destination B
- B passes datagram up protocol stack to IP

- **课本341-346页**: R4、R6、R8、P2、P3、P5、P8题
- 提交方式: <u>https://selearning.nju.edu.cn/</u>(教学支持系统)

- 命名:学号+姓名+第*章。
- 若提交遇到问题请及时发邮件或在下一次上课时反馈。

- R4. 假设两个节点同时经一个速率为 R 的广播信道开始传输一个长度为 L 的分组。用 d_{prop} 表示这两个节 点之间的传播时延。如果 d_{unp} < L/R, 会出现碰撞吗?为什么?
- R6. 在 CSMA/CD 中, 在第5次碰撞后, 节点选择 K = 4 的概率有多大? 结果 K = 4 在 10 Mbps 以太网上对 应于多少秒的时延?
- R8. 如果局域网有很大的周长时,为什么令牌环协议将是低效的?

P2. 说明(举一个不同于图 6-5 的例子)二维奇偶校验能够纠正和检测单比特差错。说明(举一个例子) 某些双比特差错能够被检测但不能纠正。

P3. 假设某分组的信息部分(图6-3中的D)包含10字节,它由字符串"Networking"的8比特无符号二进制 ASCII 表示组成。对该数据计算因特网检验和。

P5. 考虑 5 比特生成多项式, G = 10011, 并且假设 D 的值为 1010101010。R 的值是什么?

- P8. 在 6.3 节中, 我们提供了时隙 ALOHA 效率推导的概要。在本习题中, 我们将完成这个推导。
 - a. 前面讲过,当有 N 个活跃节点时,时隙 ALOHA 的效率是 Np(1 p)^{N-1}。求出使这个表达式最大化的 p 值。
 - b. 使用在(a) 中求出的 p 值, 令 N 接近于无穷,求出时隙 ALOHA 的效率。(提示: 当 N 接近于无穷时,(1 1/N)^N 接近于 1/e。)

Q & A
